L3 ANSWER 1 OF 5 BIOSIS COPYRIGHT 2002 BIOSIS DUPLICATE 1
TI Sunscreens, skin photobiology, and skin cancer: The need for UVA protection and evaluation of efficacy.
AB Sunscreens are ultraviolet radiation (UVR)-absorbing chemicals that attenuate the amount and nature of UVR reaching viable cells in the skin. They are selected and tested for their ability to prevent erythema. No sunscreen prevents photodamage, as it has been demonstrated that suberythmal doses of UVR cause a variety of molecular changes (including DNA damage) in these cells. Furthermore, the spectrum of UVR reaching viable cells is altered by topically applied sunscreen. In this review, the basic aspects of sunscreens and skin photobiology are reviewed briefly. Although there can be no question concerning the efficacy of sunscreens for the prevention of erythema, questions remain because of the possible cumulative effects of chronic suberythmal doses and the increased exposure of skin cells to longer UVR wavelengths. The current major issue surrounding sunscreens involves their ability to protect skin cells against the effects of UVA radiation. These UVA effects may be direct damage (base oxidations) or effects on the skin immune system, yet there is no uniformly accepted method for the evaluation of UVA protection. This review is focused primarily on the latter topic covering action spectra that implicate the need for UVA protection. In addition, in vivo and in vitro methods proposed for the evaluation of candidate **sunscreen formulations** of UVA protective ability are reviewed. Finally, revisions in the terminology used to describe the protection afforded by sunscreens are suggested. It is proposed that SPF ("sun" protection factor) be renamed "sunburn" protection factor and that "critical wavelength" be designated "long wave index."

L3 ANSWER 2 OF 5 CAPLUS COPYRIGHT 2002 ACS
TI Transgenic animals having modified hedgehog signal transduction for therapeutic applications in cancer therapy and **sunscreen formulations**
AB The present invention provides transgenic animals in which the normal biol. function of one or more tumor suppressors of the patched gene family (herein "ptc gene") have been functionally inactivated such that, while viable at birth and into adulthood, the animal can be induced to form basal cell carcinomas at a significantly higher frequency relative to the wild-type animal, as for example, upon exposure to DNA damaging agents such as non-ionizing (e.g., UV) or ionizing radiation. Patched gene disruption was achieved by crossing over and homologous recombination and insertion recombination. As described in the pending examples, the heterozygous ptc knockout mice are viable at birth, but are susceptible to higher incidence of cancers when contacted with DNA damaging agents. A salient feature of these animals is that the mice can be induced to form basal cell carcinomas which, histol., are similar to BCC in humans. These transgenic animals have a heterozygous patched

loss-of-function phenotype or heterozygous smoothened gain-of-function phenotype. Homozygous animals are also generated. Hyperproliferative skin cell growth is monitored in the presence of an anti-proliferative test agent in patched +/- mice. This Hh-Ptc pathway may provide new diagnostic tools and new insights into tumorigenesis that can be directed toward potential therapies.

L3 ANSWER 4 OF 5 CAPLUS COPYRIGHT 2002 ACS
TI Enhancement of **DNA** repair of UV damage in mouse and human skin by liposomes containing a **DNA** repair enzyme
AB The **DNA** repair enzyme T4 endonuclease V was encapsulated in liposomes to enhance repair of pyrimidine dimers formed in **DNA** by UV. Addn. of the liposomes to human epidermal keratinocytes in culture increased the removal of **DNA** damage, as measured by loss of endonuclease-sensitive sites, and enhanced **DNA** repair synthesis,

as measured by an increase in unscheduled **DNA** synthesis. Topical treatment of UV-irradiated SKH-1 hairless mice with liposomes increased the removal of pyrimidine dimers from epidermal **DNA**. The results demonstrate that topical application of liposomes contg. T4 endonuclease V may enhance **DNA** repair when applied to lotion either before or after UV exposure. The results suggest that liposomes contg. T4 endonuclease V can be included in either **sunscreen formulations** or in cosmetic prepsns. for regular use to repair **DNA** damage from exposure to solar UV.

TI Sunscreen predictive assays. Alternative assays that measure the ability of different sunscreens to protect against epidermal and dermal effects of ultraviolet irradiation

AB The mouse epidermal **DNA** synthesis, the mouse epidermal ornithine decarboxylase (ODC) [9024-60-6], the mouse skin edema, the spectrophotometric absorption, and the human sun protection factor (SPF) assays were used to evaluate 4 **sunscreen formulations** (Total Eclipse 15, PreSun 15, PreSun 8, and Homosalate). The mouse epidermal **DNA** synthesis assay showed that p-aminobenzoic acid ester-contg. sunscreens (Total Eclipse) was less protective for UV effect on epidermal **DNA** than p-aminobenzoic acid [150-13-0]-contg. sunscreens (PreSun 15). The SPF predicted by the ODC assay correlated well with human erythema SPF, mouse skin edema and in vitro spectrophotometric absorption.
